Title	New Formaldehyde-Free Adhesives for Wood Manufacturing: In Vitro Evaluation of Potential Toxicity of Fine Dust from Wood Sawing
Source type	Paper
Link / File	PMID: 34968639
Craft applicability	Wood
Primary Why-theme	10. Repair (Failure, Repair and Quality)
Process stage	Repair / adhesive selection
Questions answered / generated	Why does the chemical composition of a wood adhesive matter for safety? Why might formaldehyde-based adhesives pose a health risk compared to alternatives?
Evidence level	E3 (direct scientific evidence, in vitro toxicology; indirect proxy for food-contact migration specifically)
Relevance note	Provides experimental toxicity evidence that adhesive chemistry (e.g., formaldehyde-based resins) carries real health risk via dust/emissions, supporting the broader reasoning behind the report's caution on repair-material selection. Note: this study addresses inhalation exposure during sawing, not direct food-contact migration — it complements but does not replace the WBC-0011 regulatory source.
