Title	Generation Rate and Particle Size Distribution of Wood Dust by Handheld Sanding Operation
Source type	Paper
Link / File	DOI: 10.1539/joh.16-0136-BR
Craft applicability	Wood (likely comparable for bamboo dust, though not directly tested)
Primary Why-theme	8. Dust and Respiratory Exposure
Process stage	Finishing (machine paper-finishing + final hand sanding)
Questions answered / generated	Why does sanding — machine or hand — generate significant airborne wood dust? What quantity and particle size of dust is produced during handheld sanding?
Evidence level	E3 (direct scientific evidence, measured exposure data)
Relevance note	IIT process documentation confirms the Udayagiri sequence uses a powered paper-finishing machine followed by a final manual hand-sanding step. This study directly measures exposure from powered handheld sanding, closely matching the machine-finishing stage; it serves as a reasonable but indirect proxy for the subsequent manual hand-sanding stage, where dust generation is expected to be lower but has not been separately measured.
