Title	Analyzing the Impact of Veneer Layup Direction and Heat Treatment on Plywood Strain Distribution During Bending Load by Digital Image Correlation (DIC) Technique
Source type	Paper
Link / File	https://www.sciencedirect.com/science/article/pii/S2238785423027540
Craft applicability	Wood (proposed CLT/LVL base with thin walnut veneer facing)
Primary Why-theme	11. Product Function, Use and Performance
Process stage	Material augmentation (proposed engineered-wood base structure)
Questions answered	Why would a laminated (CLT/LVL) core with a thin walnut veneer face offer better dimensional stability and reduced cracking than solid walnut panels?
Evidence level	E3
Relevance note	Shows that veneer layup structure and layering directly govern dimensional stability and strain distribution under load, supporting the report's proposal that CLT/LVL cores with thin walnut veneer surfaces would offer higher dimensional stability, lower cost, and reduced cracking/warping compared to solid seasoned walnut.
